Statistical Natural Language Processing ML intro & regression

Çağrı Çöltekin

University of Tübingen Seminar für Sprachwissenschaft

Summer Semester 2019

Machine learning is ...

The field of machine learning is concerned with the question of how to construct computer programs that automatically improve with experience.

—Mitchell (1997)

Machine Learning is the study of data-driven methods capable of mimicking, understanding and aiding human and biological information processing tasks.

—Barber (2012)

Statistical learning refers to a vast set of tools for understanding data.

—James et al. (2013)

Supervised learning

. Çöltekin, SfS / University of Tübingen

Summer Semester 2019

IL intro Models Parameter estimation Evaluation Non-linearity Overfitting & regularization Gradient descent Categorical predictor

Supervised learning

two common settings

An ML algorithm is called

regression if the outcome to be predicted is a numeric (continuous) variable

 $\ensuremath{\textit{classification}}$ if the outcome to be predicted is a categorical variable

Why machine learning?

- Majority of the modern computational linguistic tasks and applications are based on machine learning
 - Tokenization
 - Part of speech tagging
 - Parsing
 - ...
 - Speech recognition
 - Named Entity recognition
 - Document classificationQuestion answering
 - Machine translation
 - ...

Summer Semester 20:

1/4

intro Models Parameter estimation Evaluation Non-linearity Overfitting & regularization Gradient descent Categori

Supervised or unsupervised

- Machine learning methods are often divided into two broad categories: *supervised* and *unsupervised*
- Supervised methods rely on labeled (or annotated) data
- Unsupervised methods try to find regularities in the data without any (direct) supervision
- Some methods do not fit any (or fit both):
 - Semi-supervised methods use a mixture of both
 - Reinforcement learning refers to the methods where supervision is indirect and/or delayed

In this course, we will mostly discuss/use supervised methods.

Ç. Çöltekin, SfS / University of Tübingen

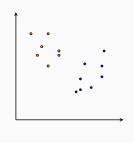

Summer Semester 2019

9 3 / 42

ML intro Models Parameter estimation Evaluation Non-linearity Overfitting & regularization Gradient descent Categorical p

Unsupervised learning

- In unsupervised learning we do not have any labels
- The aim is discovering some 'latent' structure in the data
- Common examples include
 - Clustering
 - Density estimation
 - Dimensionality reduction
- In NLP, methods that do not require (manual) annotation are sometimes called unsupervised

Classification

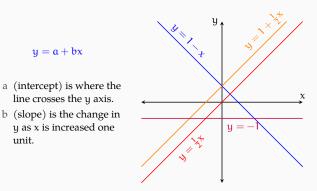

Machine learning and statistics

- The methods largely overlap (it was even suggested that both should be collectively called 'data science')
- · Aims differ
 - In statistics (used as in experimental sciences) aim is making inferences using the models
 - In machine learning correct predictions are at the focus
- · A more diverse set of models/methods are used in ML

Ç. Çöltekin, SfS / University of Tübinge

ML intro Models Parameter estimation Evaluation Non-linearity Overfitting & reg

The linear equation: the regression model

Ç. Çöltekin, SfS / University of Tübinger

unit.

$y_i = wx_i$

Notation differences for the regression equation

- \bullet Sometimes, Greek letters α and β are used for intercept and the slope, respectively
- Another common notation to use only b, β , θ or w, but use subscripts, 0 indicating the intercept and 1 indicating the
- In machine learning it is common to use w for all coefficients (sometimes you may see b used instead of w_0)
- · Sometimes coefficients wear hats, to emphasize that they are estimates
- Often, we use the vector notation for both input(s) and coefficients: $\mathbf{w} = (w_0, w_1)$ and $\mathbf{x_i} = (1, x_i)$

ML topics we will cover in this course

- (Linear) Regression (today)
- Classification (perceptron, logistic regression, ANNs)
- Evaluation ML methods / algorithms
- Unsupervised learning
- · Sequence learning

ML intro Models Parameter estimation Evaluation Non-linearity Overfitting & reg-

Machine learning and models

- A machine learning method makes its predictions based
- The models are often parametrized: a set of parameters defines a model
- · Learning can be viewed as finding the 'best' model among a family of models (that differ based on their parameters)

Ç. Çöltekin, SfS / University of Tübing

The simple linear model

some terminology

$$y_i = a + bx_i$$

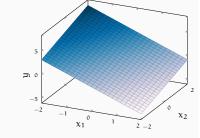

- y is the *outcome* (or response, or dependent) variable. The index i represents each unit observation/measurement (sometimes called a 'case')
- x is the *predictor* (or explanatory, or independent) variable
- a is the *intercept* (called *bias* in the NN literature)
- b is the slope of the regression line.

a and b are called coefficients or parameters

a + bx is the model's prediction of $y(\hat{y})$, given x

Regression models with multiple predictors

- The equation defines a (hyper)plane
- With 2 predictors: $y = w_0 + w_1 x_1 + w_2 x_2$
- With more predictors it is more convenient to use vector notation: y = wx

Parameter estimation for regression

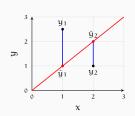

Parameter estimation

- In ML, we are interested in finding the best model based
- · Learning is selecting a model from a family of models that differ in their parameters
- Typically, we seek the parameters that reduce the prediction error on a training set
- Ultimately, we seek models that do not only do well on the training data, but also new, unseen instances

ML intro Models Parameter estimation Evaluation Non-linearity Overfitting & regularization

Estimating regression parameters

- We view learning as a search for the regression equation with least error
- The error terms are also called residuals
- We want error to be low for the whole training set: average (or sum) of the error has to be reduced
- Can we minimize the sum of the errors?

$$y_i = \underbrace{w_0 + w_1 x_i}_{\hat{y}_i} + \epsilon$$

Ç. Çöltekin, SfS / University of Tübing

Models Parameter estimation Evaluation Non-linearity Overfitting & regularization Gra

Short digression: minimizing functions

In least squares regression, we want to find w_0 and w_1 values that minimize

$$E(w) = \sum_{i} (y_i - (w_0 + w_1 x_i))^2$$

- Note that E(w) is a *quadratic* function of $w = (w_0, w_1)$
- As a result, E(w) is *convex* and have a single extreme value - there is a unique solution for our minimization problem
- In case of least squares regression, there is an analytic solution
- · Even if we do not have an analytic solution, if the error function is convex, a search procedure like gradient descent can still find the global minimum

Ç. Çöltekin, SfS / University of Tübingen

ML intro Models Parameter estimation Evaluation Non-linearity Overfitting & regularization Gradient de

Regression with multiple predictors

$$y_i = \underbrace{w_0 + w_1 x_{i,1} + w_2 x_{i,2} + \dots + w_k x_{i,k}}_{\hat{y}} + \varepsilon_i = w x_i + \varepsilon_i$$

 w_0 is the intercept (as before).

 $w_{1..k}$ are the coefficients of the respective predictors.

- ε is the error term (residual).
- · using vector notation the equation becomes:

$$y_i = wx_i + \epsilon_i$$

where
$$\mathbf{w} = (w_0, w_1, \dots, w_k)$$
 and $\mathbf{x_i} = \left(1, x_{i,1}, \dots, x_{i,k}\right)$

It is a generalization of simple regression with some additional power and complexity.

Least-squares regression

• Find w_0 and w_1 , that minimize the sum of the squared errors

$$E(\mathbf{w}) = \sum_{i} \varepsilon_{i}^{2} = \sum_{i} (y_{i} - \hat{y}_{i})^{2} = \sum_{i} (y_{i} - (w_{0} + w_{1}x_{i}))^{2}$$

• We can minimize E(w) analytically

$$w_1 = \frac{\sigma_{xy}}{\sigma_x^2} = r \frac{s d_y}{s d_x} \qquad w_0 = \bar{y} - w_1 \bar{x}$$

Ç. Çöltekin, SfS / University of Tübing

What is special about least-squares?

- Minimizing MSE (or SS_R) is equivalent to MLE estimate under the assumption $\varepsilon \sim \mathcal{N}(0,\sigma^2)$
- Working with 'minus log likelihood' is more convenient

$$\mathsf{E}(w) = -\log \mathcal{L}(w) = -\log \prod_{i} \frac{e^{-\frac{(y_{i} - \hat{y}_{i})^{2}}{2\sigma^{2}}}}{\sigma \sqrt{2\pi}}$$

$$\hat{\boldsymbol{w}} = \operatorname*{arg\,min}_{\boldsymbol{w}} (-\log \mathcal{L}(\boldsymbol{w})) = \operatorname*{arg\,min}_{\boldsymbol{w}} \sum_{i} (y_i - \hat{y}_i)^2$$

- There are other error functions, e.g., absolute value of the errors, that can be used (and used in practice)
- One can also estimate regression parameters using Bayesian estimation

Ç. Çöltekin, SfS / University of Tübinge

Evaluating machine learning systems

- Any (machine learning) system needs a way to measure its success
- For measuring success (or failure) in a machine learning system we need quantitative measures
- Remember that we need to measure the success outside the training data

Ç. Çöltekin, SfS / University of Tübinge Ç. Çöltekin, SfS / University of Tübingen

We can express the variation explained by a regression model

• In simple regression, it is the square of the correlation coefficient between the outcome and the predictor

• $100 \times R^2$ is interpreted as 'the percentage of variance

 R² shows how well the model fits to the data: closer the data points to the regression line, higher the value of R²

Explained variation

Total variation

Measuring success in Regression

• Root-mean-square error (RMSE)

$$\text{RMSE} = \sqrt{\frac{1}{n}\sum_{i}^{n}(y_{i} - \hat{y}_{i})^{2}}$$

measures average error in the units compatible with the outcome variable.

• Another well-known measure is the *coefficient of determination*

$$R^2 = \frac{\sum_i^n (\hat{y}_i - \bar{y})^2}{\sum_i^n (y_i - \bar{y})^2} = 1 - \left(\frac{RMSE}{\sigma_y}\right)^2$$

ML intro Models Parameter estimation Evaluation Non-linearity Overfitting & regularization Gradient descent Categorical predictor

Example: polynomial basis functions

ML intro Models Parameter estimation Evaluation Non-linearity Overfitting & regularization Gradient descent Categorical predictor

Overfitting

demonstration through polynomial regression

Dealing with non-linearity

Assessing the model fit: R²

• The range of R² is [0, 1]

explained by the model'

as:

- \bullet Regression estimation works because the regression equation is linear with respect to parameters w
- Introducing non-linear combinations of inputs does not affect the estimation procedure. The following are still linear models

$$y = w_0 + w_1 x^2 + \varepsilon$$

$$y = w_0 + w_1 \log(x) + \varepsilon$$

$$y = w_0 + w_1 x_1 + w_2 x_2 + w_3 x_1 x_2 + \varepsilon$$

- In general, we can replace input x by a function of the input(s) $\Phi(x)$. $\Phi()$ is called a *basis function*
- Basis functions allow linear models to model non-linear relations by *transforming* the input variables

Summer Semester 2019 27 /

IL intro Models Parameter estimation Evaluation Non-linearity Overfitting & regularization Gradient descent Categorical p

Overfitting

- *Overfitting* is an important problem in ML, meaning the model has learned peculiarities/noise in the data
- An overfitted model will perform well in training data, but fail on new/unseen data
- Typically 'more complex' models are more likely to overfit

Ç. Çöltekin, SfS / University of Tübingen

Summer Semester 2015 25 / 12

ML intro Models Parameter estimation Evaluation Non-linearity Overfitting & regularization Gradient descent Categorical

Preventing overfitting

- A straightforward approach is to chose a simpler model (family), e.g., by reducing the number of predictors
- More training data helps: it is difficult to overfit if number of training instances are (much) larger than the paramters
- There are other methods (one is coming on the next slide)
- We will return to this topic frequently during later lectures

n, SfS / University of Tübingen Summer Semester 2019 30 / 42 Ç. Çöltekin, SfS / University of Tübinge

Regularized parameter estimation

- Regularization is a general method for avoiding overfitting
- The idea is to constrain the parameter values in addition of minimizing the training error
- For example, the regression estimation becomes:

$$\hat{\boldsymbol{w}} = \mathop{\arg\min}_{\boldsymbol{w}} \sum_{i} (y_i - \hat{y}_i)^2 + \lambda \sum_{j=1}^k w_j^2$$

- The new part is called the regularization term, where λ is a *hyperparameter* that determines the effect of the regularization.
- In effect, we are preferring small values for the coefficients
- Note that we do not include w_0 in the regularization term

.

Summer Semester 2019

32 / 42

Summer Semester 2019

IL intro Models Parameter estimation Evaluation Non-linearity Overfitting & regularization Gradient descent Categorical predictors

L1 regularization

In L1 regularization we minimize

$$J(w) + \lambda \sum_{j=1}^{k} |w_j|$$

- \bullet The additional term is the L1-norm of the weight vector (excluding $w_0)$
- • In statistic literature the L1-regularized regression is called ${\it lasso}$
- The main difference from L2 regularization is that L1 regularization forces some values to be 0 – the resulting model is said to be 'sparse'

ML intro Models Parameter estimation Evaluation Non-linearity Overfitting & regularization Gradient descent Categorical predictor

Visualization of regularization constraints

ML intro Models Parameter estimation Evaluation Non-linearity Overfitting & regularization Gradient descent Categorical pred

Gradient descent for parameter estimation

- In many ML problems, we do not have a closed form solution for finding the minimum of the error function
- · In these cases, we use a search strategy
- *Gradient descent* is a search method for finding a minimum of a (error) function
- The general idea is to approach a minimum of the error function in small steps

$$\mathbf{w} \leftarrow \mathbf{w} - \eta \nabla \mathbf{J}(\mathbf{w})$$

 $\nabla J \;$ is the gradient of the loss function, it points to the direction of the maximum increase

 $\boldsymbol{\eta}\$ is the learning rate

L2 regularization

The form of regularization, where we minimize the regularized cost function,

$$J(w) + \lambda ||w||^2$$

is called L2 regularization.

- Note that we are minimizing the L2-norm of the weight vector
- \bullet In statistic literature L2-regularized regression is called $\it ridge\ regression$
- The method is general: it can be applied to other ML methods as well
- $\bullet\,$ The choice of λ is important
- Note that the scale of the input becomes important

IL intro Models Parameter estimation Evaluation Non-linearity Overfitting & regularization Gradient descent Categorical p

Regularization as constrained optimization

L1 and L2 regularization can be viewed as minimization with constraints

L2 regularization

Minimize J(w) with constraint ||w|| < s

L1 regularization

Minimize J(w) with constraint $||w||_1 < s$

ML intro Models Parameter estimation Evaluation Non-linearity Overfitting & regularization Gradient descent

Regularization: some remarks

- · Regularization prevents overfitting
- The *hyperparameter* λ needs to be determined
 - best value is found typically using a grid search, or a random search
 - it is tuned on an additional partition of the data, development set
 - development set cannot overlap with training or test set
- The regularization terms can be interpreted as priors in a Bayesian setting
- Particularly, L2 regularization is equivalent to a normal prior with zero mean

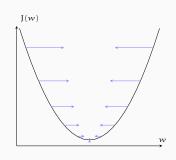

. Çöltekin, SfS / University of Tübinger

Summer Semester 2019 37

ML intro Models Parameter estimation Evaluation Non-linearity Overfitting & regularization Gradient descent Categorical p

Gradient descent with single parameter

- For a single parameter, gradient is a one-dimensional vector
- The direction of gradient is towards the maximum increase
- We take steps proportional to $-\nabla J(w)$
- Steeper the curve, the larger the parameter update

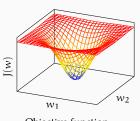

∫0 for male

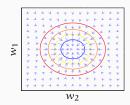

1 for female

• Categorical predictors are represented as multiple binary

• For a binary predictor, we use a single binary input. For example, (1 for one of the values, and 0 for the other)

Gradient descent with single parameter

Objective function

Negative gradients

$\bullet\,$ For a categorical predictor with k values, we use one-hot encoding (other coding schemes are possible)

$$\mathbf{x} = \begin{cases} (0,0,1) & \text{neutral} \\ (0,1,0) & \text{negative} \\ (1,0,0) & \text{positive} \end{cases}$$

Categorical predictors

coded input variables

Summary

What to remember:

- Supervised vs. unsupervised learning
- · Regression vs. classification
- · Linear regression equation
- Least-square estimate
- MSE, R²
- · non-linearity & basis functions
- L1 & L2 regularization (lasso and ridge)
